

Mongo Aggregation queries

With reference to the completed mongo queries from aggregation folder in the github:

Write a query on books collection which will use all the aggregation operators like sort, skip, limit, project, match, unwind in a single query. Task is to create a use case which we can apply on books collections and use all the aggregation operators in a single query. You can create any use case from the books collection.

Note: You can add more number of fields to the collection if you like to create a use case.
